DiRT2 DirectX 11 Technology

Gareth Thomas, Codemasters
Jon Story, AMD

Agenda

- ⌚ DirectX Comparison Video
- ⌚ Porting to DirectX 11
- ⌚ Tessellation Features
- ⌚ DirectCompute HDAO
- ⌚ Shadows using GatherCmp()
- ⌚ Free Threaded Resource Loading
- ⌚ Summary

DirectX Comparison Video

Porting to DirectX 11

- ⌚ Render API already abstracted for multiple platforms:
PC, Xbox360, PS3, Wii
- ⌚ Platform independent APIs for:
Buffers, Shaders, Textures,
Render States, Drawing
- ⌚ Rendering layer automatically handled:
Vertex Decls, Shader Constants,
Multisampled Render Targets

Getting Started

- ④ Dynamically loaded DX11 DLL, so we could live with a single EXE
Windows XP, Vista & Win7
- ④ On start up we attempt creation of a DX11 device
- ④ If that fails then we fall back to a DX9 device
- ④ We actually kept our original DX9 device enumeration code – this worked out fine

The Dumb Port 😊

- ⌚ Wanted to get 2D and static 3D objects on screen
- ⌚ In place creation and destruction of state objects
 - Very slow 😞 – but got quick visual results
- ⌚ Large constant buffer updates all over the place
 - Again very slow 😞 – but got things working

The State Manager

- ⌚ Created a State Manager class
 - Hash map of state objects
- ⌚ Check all state objects for existence with the manager
 - Create and store as necessary
- ⌚ Only a handful of different state objects ever created
 - DX11 divides state objects logically
- ⌚ Only load time state object creation, ~10% performance gain

Immutable Objects

- ⌚ Static VBs & IBs must be flagged as `D3D11_USAGE_IMMUTABLE`
- ⌚ Initially this was missed
 - Caused a massive GPU frontend bottleneck
 - Gave rise to ~30% gain in baseline performance

Tackling the Constant Buffer Problem

- ⌚ Unreferenced constants & samplers are not optimized away
Different to DX9
- ⌚ Shader source was organised such that multiple shader programs lived in one source file
- ⌚ Therefore each shader would come with an enormous globals buffer
- ⌚ This gave rise to many large constant buffer updates
Very slow indeed

Constant Buffers – Solution (1)

- ④ Sort constants by frequency of update:
 - Per frame constants
 - ④ Lighting, Fog, HDR Multipliers, etc.
 - Render target constants
 - ④ Width, Height, etc.
 - Camera constants
 - ④ View, Projection, Eye, etc.
- ④ This improved the situation
 - But still lots of constants getting dragged into global buffer

Constant Buffers – Solution (2)

- ④ Wrap shader source & constant declarations with defines:
 VERTEX_SHADER, PIXEL_SHADER,
 DOMAIN_SHADER, HULL_SHADER
- ④ Pass appropriate define in when compiling shaders off-line
- ④ ~25% performance gain
- ④ Solution is still not perfect – work in progress on this problem...

Tessellated Animated Crowd – The Problem (1)

- ⌚ Crowd meshes skinned on CPU
- ⌚ Used instancing to render ~100k crowd models
- ⌚ Difficult to up the fidelity of these meshes without incurring a large cost:
 - CPU skinning cost
 - Memory footprint & bandwidth
- ⌚ We've wanted to improve quality here for some time...

Tessellated Animated Crowd – The Problem (2)

- ⌚ Current high LOD mesh uses around 800 triangles
- ⌚ Silhouette is pretty angular
- ⌚ Normal maps used to gain better lighting

Tessellated Animated Crowd – The Solution (1)

- ⊕ Used PN-Triangles technique to smooth out base mesh using the existing data set

Curved PN-Triangles by Alex Vlachos, Jörg Peters, Chas Boyd, and Jason L. Mitchell

August 09 DirectX SDK Sample: PNTriangles11

- ⊕ No new artwork required!
- ⊕ CPU skinning, memory footprint & bandwidth unchanged
- ⊕ Silhouettes much improved at tessellation factor 5

☒ Normal Map

Tessellated Animated Crowd – The Solution (2)

- ⌚ Used the normal maps as displacement maps
- ⌚ Some artwork involved to ensure no cracks in the displaced meshes
 - Wrapped texture coords cause this
- ⌚ Able to bring out nice details in hair and clothing
- ⌚ Good use of the extra triangles generated

Tessellated Animated Crowd – The Solution (2)

- ⌚ For adaptive tessellation factors we used two metrics:
 - 1) Patch size in screen space, because this worked even for camera zooms
 - 2) Distance from camera
- ⌚ We switched tessellation off for meshes rendered below the top LOD

Tessellated Cloth (1)

- ⌘ CPU based physics simulation
 - Lots of flags and border cloth material
 - ~35 vertices in base flag mesh
- ⌘ Also used a scrolling normal map for high frequency wind ripples
- ⌘ Used PN-Triangles + Displacement Mapping
- ⌘ Smoothed out the low detail mesh and added ripple details

Tessellated Cloth (2)

- ⌚ Adding real geometry also meant improved self shadowing
- ⌚ We employed the same adaptive tessellation algorithm as used for the crowd

PN-Triangles + Displacements

PN-Triangles + Displacements

Tessellated Water (1)

- ⌚ Wake simulated on CPU
- ⌚ Normals uploaded to a texture
- ⌚ Combined with scrolling ripple texture
- ⌚ In DX9 we only rendered 2 triangles and used per-pixel lighting
- ⌚ Worked quite well – but for many view positions the illusion was broken

Tessellated Water (2)

- ⦿ In DX11 we used the DS to displace the water surface
 - Sampled from the normals texture
 - Typically a 512 x 512 map
- ⦿ Resulted in a more physically accurate surface

DirectCompute HDAO

- ④ HDAO adds dynamic high quality AO over and above our pre-baked solution
- ④ HDAO is very texture heavy
- ④ Refer to this link for an explanation on how it works:
http://developer.amd.com/gpu_assets/
- ④ We used the CS to accelerate this technique...

HDAO: OFF

Post Processing the PS Way...

- The pipeline begins by executing the rendering pipeline then sampled

Overlapping Tiles (1)

- ④ Use the LDS to drastically reduce the texture sampling cost
- ④ Divide the screen up in to tiles for thread groups to process

nX Groups

nY Groups

Overlapping Tiles (2)

- Kernel size determines level of overlap

nX Groups

nY Groups

```
// Region stored in LDS
```

```
uTexelDim = 56;
```

```
uTexelOverlap = 12;
```

```
uTexelDimAfterOverlap = uTexelDim - ( 2 * uTexelOverlap );
```

```
// Compute thread groups from screen res
```

```
iGroupsX = ceil( fScreenWidth / uTexelDimAfterOverlap );
```

```
iGroupsY = ceil( fScreenHeight / uTexelDimAfterOverlap );
```

```
// Dispatch thread groups
```

```
pd3dImmediateContext->Dispatch( iGroupsX, iGroupsY, 1 );
```

Overlapping Tiles (3)

Texel sampling area,
written to LDS

ALU PP compute
area,
LDS reads/writes

kernel size

Overlapping Tiles (4)

```
// Outline code...
```

```
// CS result texture
```

```
RWTexture2D<float> g_ResultTexture : register( u0 );
```

```
// LDS
```

```
groupshared float g_LDS[TEXELS_Y][TEXELS_X];
```

```
[numthreads( THREADS_X, THREADS_Y, 1 )]
```

```
void CS_PPEffect( uint3 Gid : SV_GroupID, uint3 GTid : SV_GroupThreadID )  
{
```

```
    // Sample texel area based on group thread ID - store in LDS
```

```
    g_LDS[GTid.y][GTid.x] = fSample;
```

```
    // Enforce barrier to ensure all threads have written their
```

```
    // samples to the LDS
```

```
    GroupMemoryBarrierWithGroupSync();
```

```
    // Perform PP ALU on LDS data and write data out
```

```
    g_ResultTexture[u2ScreenPos.xy] = ComputePPEffect();
```

```
}
```

HDAO Performance

- Windows 7 64-bit, AMD Phenom II 3.0 GHz, 2 GB RAM, ATi HD5870, Catalyst 10.2

Shadows using GatherCmp()

- ⌚ DX9 renderer implemented several solutions:
 - Fetch 4 (older AMD HW)
 - PCF sampling
- ⌚ Cascaded shadow maps using D16 surfaces
- ⌚ DX11 lookups performed using GatherCmp() instruction
 - Simpler to implement
 - Only one solution 😊

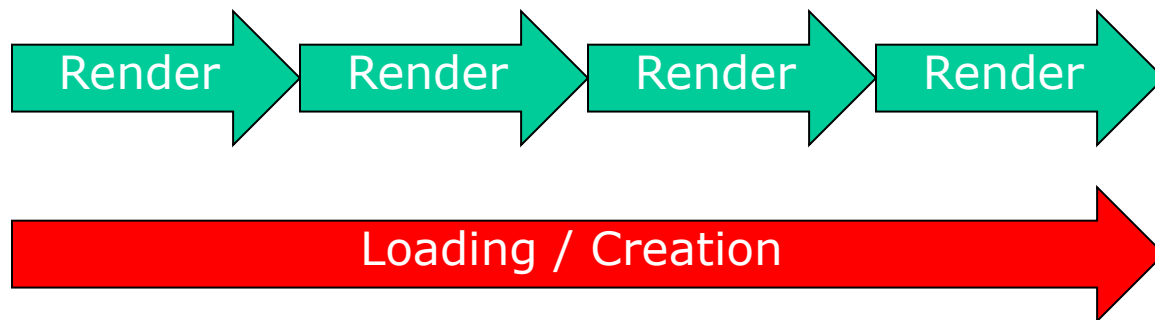

Free Threaded Resource Loading (1)

- ⌚ DiRT2 uses a background loading thread
- ⌚ Resources placed in a queue
- ⌚ In DX9 mode resources are created on the main thread

Free Threaded Resource Loading (2)

- ⌚ In DX11 mode resources are created on the loading thread
- ⌚ Simpler and faster implementation
- ⌚ Noticeably faster loading times, ~50% faster

Summary

- ⌚ A naive port to DX11 will not be fast
- ⌚ Tessellation greatly improves image quality and saves memory
- ⌚ DirectCompute can significantly improve post processing performance
- ⌚ Use free threaded resource loading to reduce loading times
- ⌚ DirectX 11 Rocks!
